1 Dataset

1.1 About Dataset

information about the data set and the three given files:

Context: This data set contains published iTRAQ proteome profiling of 77 breast cancer samples generated by the Clinical Proteomic Tumor Analysis Consortium (NCI/NIH). It contains expression values for ~12.000 proteins for each sample, with missing values present when a given protein could not be quantified in a given sample. this data was sampled from 105 originally from the TCGA (The Cancer Genome Atlas Program - NCI), which was further filtered to 77 samples containing high quality protein expression data. Content:

- File: 77cancerproteomesCPTACitraq.csv
 - RefSeqaccessionnumber: RefSeq protein ID (each protein has a unique ID in a RefSeq database)
 - **gene_symbol:** a symbol unique to each gene (every protein is encoded by some gene)
 - **gene_name:** a full name of that gene
 - Remaining columns: log2 iTRAQ ratios for each sample (protein expression data, most important), three last columns are from healthy individuals
- File: clinicaldatabreast cancer.csv
 - **First column** "Complete TCGA ID" is used to match the sample IDs in the main cancer proteomes file (see example script).
 - All other columns have self-explanatory names, contain data about the cancer classification
 of a given sample using different methods. 'PAM50 mRNA' classification is being used in the
 example script.
- File: PAM50 proteins.csv
 - Contains the list of genes and proteins used by the PAM50 classification system. The column RefSeqProteinID contains the protein IDs that can be matched with the IDs in the main protein expression data set.

Past Research: Original research paper: https://www.researchgate.net/publication/303509927_ Proteogenomics connects somatic mutations to signaling in breast cancer

Summary: the data were used to assess how the mutations in the DNA are affecting the protein expression landscape in breast cancer. Genes in our DNA are first transcribed into RNA molecules which then are translated into proteins. Changing the information content of DNA has impact on the behavior of the proteome, which is the main functional unit of cells, taking care of cell division, DNA repair, enzymatic reactions and signaling etc.

my question is: Are there different ways to categorize breast cancer based on protein expression data, with machine learning being used to classify them without using the pam50 proteins?

1.2 Exploratory Data Analysis

loading of the dataframes and showing the successful loading and its dimensions. note only the first 5 columns of "77_cancer_proteomes_CPTAC_itraq.csv" are shown since after column 4 they are the same type.

```
protein_exp_data <- read.csv(file = "../data/77_cancer_proteomes_CPTAC_itraq.csv")

clinical_data <- read.csv(file = "../data/clinical_data_breast_cancer.csv")

pam50_protein_data <- read.csv(file = "../data/PAM50_proteins.csv")

# showing successful loading of data

# only showing first 5 columns of proteomes

pander(head(protein_exp_data[1:5], n = 5))</pre>
```

GeneSymbol	Gene abbreviation	chr	NA
RefSeqProteinID	Unique reference identifier	chr	NA
Species	Species	chr	latin name
Gene.Name	Name of the gene	chr	NA

Here we can also see that everything has been successfully loaded into R

1.3 Data observation

there are 12553 rows in the data, these are proteins identifiable with a RefSeq ID number and have 86 columns of which the last 83 are samples (with their identifiers as there name and the last three from healthy individuals, but these shall not be used for the machine learning part since 3 samples is too little to use for analyzes. to further use the data I shall reshape it to make the rows samples and each column a protein.

1.4 Data cleaning and altering

altering sample names

the alteration of sample names to corespondent to the clinical data names is needed for further comparison and analyses. this is done by changing the column names to that of the same format of the clinical data. this is done with some regex magic.

```
# storing a list of the column names
column_names <- names(protein_exp_data)
# function</pre>
```

```
change_sample_name <- function (x){
    #search for TCGA name, if found split and make new name
    if(grepl("TCGA",x) == TRUE){
        temp_list <- as.list(strsplit(x, '[_|-|.]')[[1]])
        x <- str_c(c('TCGA',temp_list[[1]],temp_list[[2]]),collapse = '-')
    }
return (x)
}

# changing of the colnames
colnames(protein_exp_data) <- lapply(column_names, change_sample_name)
cat("Old name:",column_names[[4]],",New name:",names(protein_exp_data)[[4]])</pre>
```

Old name: AO.A12D.O1TCGA , New name: TCGA-AO-A12D

this output show to conversion has been successful

numerical data frame

now we need to make a data frame with only the numerical data for the ease of analyzes

```
# first making a data frame with only the numerical data, samples start at column number 4 til the end protein_exp_numerical <- protein_exp_data[4:86]
```

Transposing

transposing the created data frame "protein exp numerical", and adding the refseq ID as column name

protein exp numerical number of rows: 12553 number of columns: 83

```
cat("protein_exp__numerical_transposed number of rows:", nrow(protein_exp__numerical_transposed),
    "number of columns:", ncol(protein_exp__numerical_transposed), '\n')
```

protein_exp__numerical_transposed number of rows: 83 number of columns: 12553

as we can see the row and column dimensions have been flipped

cleaning

since there are NA values in the data lets see how much

```
count_na_func <- function(x) sum(is.na(x))
# getting NA values per RefSeqID(column)
Na_per_col <- sapply(protein_exp__numerical_transposed, count_na_func)</pre>
```

```
ggplot() +
  aes(Na_per_col) +
  geom_histogram(color = "black", fill = "#F9C000", binwidth = 3) +
  xlab("Number of NA") +
  ylab("Frequency of columns") +
  ggtitle("Frequency of number of NA values per RefSeqID")
```

Frequency of number of NA values per RefSeqID

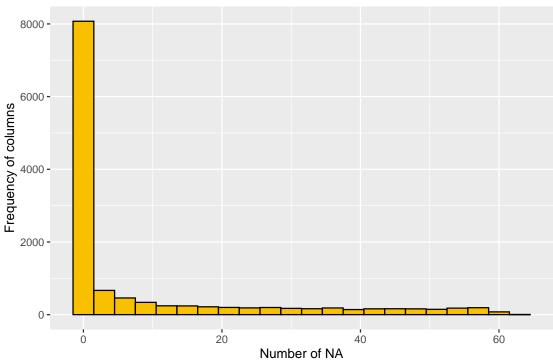

Figure 1: barplot with the frequency of columns with more than 0 NA in them

```
ggsave(
  filename = "figure1.png",
  plot = last_plot(),
  path = "../data/figures")
```

Saving 6.5 x 4.5 in image

```
ggplot() +
  aes(Na_per_col[Na_per_col > 0]) +
  geom_histogram(color = "black", fill = "#0039F9",binwidth = 3) +
  xlab("Number of NA") +
  ylab("Frequency of columns") +
  ggtitle("Frequency of number of NA values per RefSeqID with 0 omitted")
```

Frequency of number of NA values per RefSeqID with 0 omitted

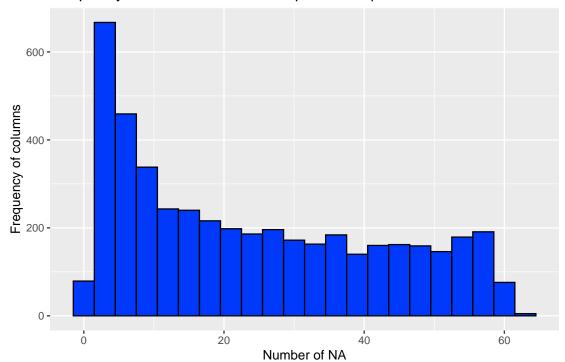

Figure 2: barplot with the frequency of columns with more than 0 NA in them

```
ggsave(
  filename = "figure2.png",
  plot = last_plot(),
  path = "../data/figures")
```

Saving 6.5×4.5 in image

there are a lot of proteins with more than 10% of their samples with missing data, so i shall be removing.

```
cat("number of proteins with NA values in them:", sum(Na_per_col > 0), '\n')
```

number of proteins with NA values in them: 4559

```
# deleting every protein with more than 10% NA values in them, since this is allot
proteomes_filtered_data <- protein_exp__numerical_transposed[Na_per_col < 8]
cat("number of proteins with 8 or more NA values in them and deleted from data:",
    sum(Na_per_col > 8), '\n')
```

number of proteins with 8 or more NA values in them and deleted from data: 3219

```
cat("proteomes_filtered_data[number of rows:",
    nrow(proteomes_filtered_data),
    "number of columns:",
    ncol(proteomes_filtered_data),'\n')
```

```
## proteomes_filtered_data[number of rows: 83 number of columns: 9199
```

as we can see from te reports generated by the code we can see that the filtering of NA was successful. and we now have a data set that contains data with less than 10% per protein of NA values

Merging clinical and protein expression dataframes

to be able to use the Clinical dat we need to merge it to its corresponding row and sample in the Protein expressions

```
## merged_data of rows: 77 number of columns: 12558
```

we can see that not every sample had an entry in the clinical data, so we end up with 6 rows of sample data that get left out of the merged data set

1.5 Data visualisation

Showing some examples of distributions of protein expression data since there are around 12 000 proteins found

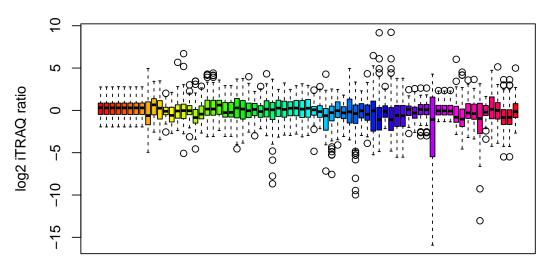

```
ggsave(
  filename = "figure3.png",
  plot = last_plot(),
  path = "../data/figures")
```

```
## Saving 6.5 \times 4.5 in image
```

Since i can't be sure of the significante of every protein i cant simple trow away any sample

to fix this i shall get the standard deviation from every protein to prepare for a selection of the most deviant ones. and for illustration i will overlay the dataframe which has been filtered from most NA values

distribution of Protein expression for first 70 Proteins

Protein

Figure 3: boxplot of protein expression distribution, first 70 proteins

```
fg <- colSds(as.matrix(merged_data[sapply(merged_data, is.numeric)]), na.rm = TRUE)</pre>
fg2 <- colSds(as.matrix(cleaned_merge_data[sapply(cleaned_merge_data, is.numeric)]), na.rm = TRUE)
fg <- as.data.frame(fg, row.names = colnames(merged_data[6:ncol(merged_data)]))</pre>
fg2 <- as.data.frame(fg2, row.names = colnames(cleaned_merge_data[6:ncol(cleaned_merge_data)]))
fg$count <- seq(from = 1, to = nrow(fg))
merged_fg <- merge(fg,fg2,all.x = TRUE, by = 0)</pre>
merged_fg <- merged_fg[order(merged_fg$count),]</pre>
# assigning 0 to every NA values in fg2 since that is the filterd one
merged_fg$fg2[is.na(merged_fg$fg2)] <- 0</pre>
# plotting
ggplot(data=merged_fg) +
  geom_point(size=0.0015, aes(x=count, y=fg, color="Non Na filtered")) +
  geom_point(size=0.0015, aes(x=count,y=fg2, color="Na filtered")) +
  labs(x = "Data Frame row number",
         y = "Standard deviation",
         color = "Legend") +
  ggtitle("Density plot for standard deviation of protein expression") +
  theme(legend.position = "bottom")
```

Density plot for standard deviation of protein expression

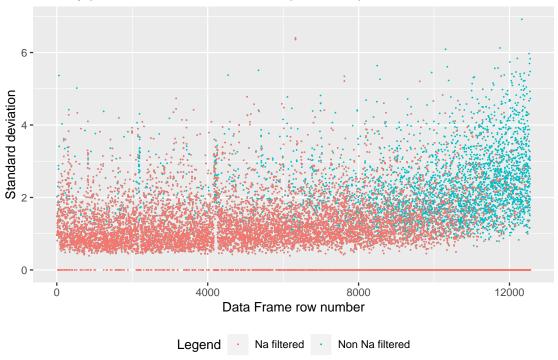

Figure 4: scatterplot of standard deviation for the protein expression data and for the NA filterd version

```
ggsave(
  filename = "figure4.png",
  plot = last_plot(),
  path = "../data/figures")
```

Saving 6.5 x 4.5 in image

as we can see in the standard deviation compared from proteins with a lot of samples with NA in them to the filtered data, we see that the proteins with allot of NA in them seem to be having a higher Standard deviation, but still ther should be enough deviation in the filtered Data.

```
# assigning as factors
merged_data$Tumor <- factor(merged_data$Tumor)
merged_data$Vital.Status <- factor(merged_data$Vital.Status)
merged_data$AJCC.Stage <- factor(merged_data$AJCC.Stage)

cleaned_merge_data$Tumor <- factor(cleaned_merge_data$Tumor)
cleaned_merge_data$Vital.Status <- factor(cleaned_merge_data$Vital.Status)
cleaned_merge_data$AJCC.Stage <- factor(cleaned_merge_data$AJCC.Stage)

write.arff(merged_data, file = "../data/merged_data.arff")
write.arff(cleaned_merge_data, file = "../data/cleaned_merge_data.arff")</pre>
```
